Suzanne R Pfeffer

ABSTRACT

To validate a genome wide CRISPR screen, we select the top hits and create lentiviruses to validate the hits. Rather than screening each virus from single cell clones, we analyze the infected cells as pools according to the following protocol. This method involves three major steps:

1. Create Cas9-expressing 3T3 cells (1-3 months)
2. Make lentiviruses that carry sgRNA (2 weeks)
3. Infect 3T3-Cas9 cells and assess gRNA efficiency (1 week)

CREATED

Nov 25, 2022

Speciality reagents

Cell culture reagents:

Low passage NIH-3T3-flpin cells (Life Technologies)
 DMEM medium with Glutamate (Hyclone)
 100X Non essential amino acids (Hyclone)
 100X Penicillin-Streptomycin (Hyclone)
 100X Sodium Pyruvate (Hyclone)
 Fetal calf Serum (Sigma)
 Blasticidin (Invivogen)
 Puromycin (Invivogen)

Molecular Biology reagents:-

Bsmb1-v2 and r3.1 buffer (NEB)
 Dh5Alpha competent cells (Life Technologies)
 Cell sorter (Sony)
 Mouse anti-Cas9 Clone (Sigma 7A9-3A3)
 Mouse anti-GRK2 (Santa Cruz E7)
 T7 ligase and T4 (salt) ligase (NEB)
 T4 Polynucleotide kinase (PNK) (NEB)
 Recombinant shrimp alkaline phosphatase (rSAP, NEB)

Plasmids and Oligos:-

Lenti-Cas9 (Addgene 52962)
 Lenti-guide puro (Addgene 52963)
 Lenti-guide puro with sgRNA_GRK2
 (CCAGGTCCGAGATTCTACA, Pusapati et al 2018)
 Lenti-CRISPR-V2 (Addgene 52961)
 PsPax2 (Addgene 12260)
 VSV-G (Addgene 12259)
 Oligos for colony PCR (PAN facility, Stanford)
 Oligos for knockout genotyping (PAN facility, Stanford)
 Oligos to clone sgRNA (PAN facility, Stanford)

Create 3T3-Cas9 cells and Clone the CRISPR guides

1 Generate 3T3-Cas9 cells

Infect NIH3T3-flpin cells with Cas9-containing lentivirus to generate cells constitutively expressing Cas9 as follows:

1. Plate NIH-3T3 cells into a 6 well cell dish at 1x10⁵ cells / well
2. After cells attach, add lentivirus made from Lenti-Cas9 vector onto the cells
[\(dx.doi.org/10.17504/protocols.io.bp2l61z2zvqe/v1\)](https://doi.org/10.17504/protocols.io.bp2l61z2zvqe/v1)

3. After  48:00:00, trypsinize cells and plate into 3 wells of a 6 well plate in media containing 10µg/ml Blasticidin
4. Cells infected with Lenti-Cas9 will survive Blasticidin and  72:00:00 after treatment, selection is stopped and Blasticidin-resistant survivors are expanded in normal medium
 - Cas9 is toxic to these cells and they grow slower than the parental cells; These cells are more sensitive to cell death than usual and care must be taken to passage them regularly at 80% confluency. Change medium every 48 hours and avoid high passage numbers
1. At this point, test cells for Cas9 expression by western blot using mouse anti-Cas9 antibody (Biolegend 844302)
2. Sort 3T3-Cas9 cells to obtain single cells in a 96 well plate using a cell sorter; Allow cells to grow for 3 weeks with occasional medium exchange
 - Cells that are grown in 25% conditioned medium (previous 3-day old 3T3 medium passed through a 0.2µm filter) grow faster
 - Glutamax instead of Glutamine also helps cells grow faster
 - Transfer clones that grow into 24 well plates and a few days later, into 6 well plates
 - Expand each clone and freeze cells in liquid nitrogen

2 Identify the best 3T3 Cas9 clones

Healthy clones appear fibroblast-like, without vacuoles, and grow at a rate such that they need a 1:5 split every 3 days. Expand such clones and test for Cas9 expression by lysing in RIPA buffer and performing a western blot using anti-Cas9 antibody

Retain cells expressing the highest Cas9 and marker of choice (in our case, phospho-Rab10); of those, select clones that have the best growth and morphology

Test the top two clones for Cas9 activity by introducing a validated sgRNA known to produce knock-outs efficiently as follows:

1. Plate each 3T3 cell clone in wells of a 6 well plate (as above)
2. Infect cells 8 h after plating with a lentivirus carrying sgRNA targeting mouse GRK2 (Pusapati et al. 2018) that is known to knock-out GRK2 efficiently; perform an additional mock infection as a control
3. After  00:00:00, remove the virus supernatant, trypsinize cells and split cells into 2 wells of a 6 well plate and culture with 1µg/ml Puromycin. Cells not infected with the gRNA lentivirus will die within  72:00:00 while resistant survivors grow
4. Exchange the growth medium with puromycin-free medium to allow cell expansion; depending on the virus titre, allow 3 days for cells to grow
5. At confluency, lyse cells and test the knock-out efficiency by western blot using a mouse anti-target antibody, in this case, anti-GRK2 antibody

Shown above is a western blot carried out to determine the level of Cas9 in each clone. We also compared levels of phosphorylated Rab10 and total Rab10 to include in the evaluation of clone preference. -ns refers to a non-specific band detected by the antibody; tubulin is analyzed as a loading control.

Shown above is a western blot of 3T3 cell clones expressing Cas9. The best clone is one that displays a good knock-out of GRK2, survives puromycin selection and recovers quickly after medium exchange and shows a healthy fibroblast-like morphology. In this example, clones H6 and B6 yielded good knockout; the blot above confirms good Cas9 expression.

3 Clone gRNA Vector

1. Digest Lenti-guide puro using Esp3I or BsmB1-V2 enzyme as follows:

(Lenti-CRISPR-V2 can also be digested using the same enzyme)

- Incubate in a PCR machine as follows:

16°C	16 hrs
37°C	1 h
4°C	hold

- Transform 5µl of the 10µl reaction into Dh5alpha competent cells
- Plate onto carbenicillin agar plates overnight
- To assess cloning efficiency, perform a colony PCR on the colonies 18 hr after transformation using the primers:

A	B
Forward	5' ATCATATGCTTACCGTAACTTGAAAGTATTTTCG
Reverse	5' GACTCGGTGCCACTTTTTCAAG

- Pick a colony using a sterile tip and dilute into 10µl of Luria broth in a PCR tube
- Amplify a plasmid that has a guide cloned into the vector as a positive control
- Amplify a Bsmbl digested plasmid as a negative control
- Amplify a colony from a control plate that didn't receive an insert as a negative control
- Amplify the uncut plasmid as a negative control

These are the conditions for amplification of these plasmids:

A	B
Green GoTaq master mix 2X	12.5µl
Primer-Forward(10µM)	1µl
Primer-Reverse(10µM)	1µl
Bacterial suspension (diluted into 10µl)	1µl
Water	9.5µl

- The green GoTaq PCR mix is ready to load onto a 2% agarose gel immediately after PCR
- The correct sized product is ~166bp
- Don't forget to use a positive control (a cloned gRNA vector - 166bp band) and a negative control (uncut original lenti guide puro vector - 2kb band)
- Dilute the crude PCR product 1:10 and send for Sanger sequencing using the forward or reverse primer used for colony PCR
- Grow colonies that show the right sized band overnight at 37°C in 50µg/ml carbenicillin and perform a plasmid mini-prep
- Use the cloned plasmid for small scale lentivirus generation ([dx.doi.org/10.17504/protocols.io.bp2l61z2zvqe/v1](https://doi.org/10.17504/protocols.io.bp2l61z2zvqe/v1)) if the Sanger sequencing shows the correct gRNA sequence has been cloned into the vector

Create pooled knock-out 3T3 cells

- 4
 - Plate 1x10⁵ 3T3-Cas9 cells in one well of a 6 well plate containing 2ml complete DMEM medium (10% fetal bovine serum, pen/strep and Glutamax)
 - After 6 hours, add 0.5ml gRNA lentivirus plus 4µg/ml polybrene
 - After 48 h, trypsinize and split the cells into 2 wells of a 6 well plate with 1 µg/ml puromycin
 - After an additional 48-72 h, exchange the medium with complete DMEM without puromycin and let the cells grow for 2 more days
 - At 80% confluence, trypsinize and plate 5x10⁴ cells on coverslips in each well of a 24 well plate
 - At the same time, take 20µl of the trypsinized cells and mix in 20µl QuickExtract solution to extract genomic DNA for knock out genotyping
 - Perform QuickExtract genomic extraction for parental wild type 3T3 and lentivirus-gRNA infected cells
 - Extract DNA according to this modified manufacturer's protocol

(Some protocols suggest 65°C for 10 min and that also works)

- PCR amplify a region around the gRNA-Cas9 cut site using genotyping PCR primers designed such that ~300-500bp are covered around the guide target site

For the gRNA used in the above example targeting mouse Rab12:

A	B
Forward	CCAAGGCCATGGTCATTCTTGATG
Reverse	TTACAACCCCAAACACTTGTTCCG

If the PCR band is of the correct size, dilute the sample 1:10 and Sanger sequence the crude PCR product using the reverse primer from the PCR

- Perform TIDE analysis (www.tide.nki.nl) or Synthego ICE analysis using the raw chromatograms in the .abi file provided with the sequencing results
- Percentage of cells with insertions or deletions (INDELs) is a proxy for knock-out efficiency
- The higher the percentage, the better the knock-out efficiency
- If needed, cells can be single cell sorted to create clonal knock-out lines for long term studies of the phenotype
- For 3T3 cells, increased passage number can be detrimental to cell physiology
- Best gRNAs with highest INDEL percentages are analyzed for the desired phenotype(s)
- Using the above mentioned gRNA directed against mouse Rab12, within 5 days we observed 80% efficiency
- Cells can be single cell sorted into 96 well plate using a Sony cell sorter at this point to create clonal cell lines with gene knock-outs
